Image Processing using Graphs

Filip Malmberg
In recent years, graphs have emerged as a unified representation for image analysis and processing. In this course, we will give an overview of recent developments in this field.

How and why do we represent images as graphs?

Graph-based methods for:

- Segmentation
- Filtering
- Classification and clustering
What will we learn in this course?

“Having a drivers license does not mean that you know how to drive a car. It means that you can drive well enough to start practicing on your own.”

—Bosse, My driving teacher.

My ambition is that after taking this course, you should be able to study graph-based image processing on your own!
About the course

http://www.cb.uu.se/~filip/ImageProcessingUsingGraphs/

- 11 Lectures. (non-mandatory)
- Examination in the form of an individual project.
Teachers

- Filip Malmberg, UU
- Alexandre Falcão, Institute of Computing, State University of Campinas, Brazil
- Erik Wernersson, UU
Project work

- Each participant should also select a topic for her individual project. The project can be applied or theoretical.
- When you have decided on a topic, discuss this with Filip to ensure that the scope is appropriate.
- Your work should be presented as a written report (~4 pages).
- Submit your report to me (Filip) no later than June 1.
- The final reports will be published on the course webpage.
What is an image?

“We will sometimes regard a *picture* as being a real-valued, non-negative function of two real variables; the value of this function at a point will be called the *gray-level* of the picture at the point.”

What is a digital image?

Storing the (continuous) image in a computer requires digitization, e.g.

- Sampling (recording image values at a finite set of *sampling points*).
- Quantization (discretizing the continuous function values).

Typically, sampling points are located on a Cartesian grid.
Generalized images

This basic model can be generalized in several ways:

- Generalized image modalities (e.g., multispectral images)
- Generalized image domains (e.g. video, volume images)
- Generalized sampling point distributions (e.g. non-Cartesian grids)

The methods we develop in image analysis should (ideally) be able to handle this.
Why graph-based?

- Discrete and mathematically simple representation that lends itself well to the development of efficient and provably correct methods.
- A minimalistic image representation – flexibility in representing different types of images.
- A *lot* of work has been done on graph theory in other applications, we can re-use existing algorithms and theorems developed for other fields in image analysis!
Euler and the seven bridges of Konigsberg

Wikipedia: “The city of Königsberg in Prussia (now Kaliningrad, Russia) was set on both sides of the Pregel River, and included two large islands which were connected to each other and the mainland by seven bridges. The problem was to find a walk through the city that would cross each bridge once and only once.”

Figure 1: Königsberg in 1652.
Euler and the seven bridges of Konigsberg

In 1735, Euler published the paper “Solutio problematis ad geometriam situs pertinentis“ (“The solution of a problem relating to the geometry of position”), showing that the problem had no solution. This is regarded as the first paper in graph theory.

Figure 2: The seven bridges of Konigsberg, as drawn by Leonhard Euler.
Graphs, basic definition

- A graph is a pair $G = (V, E)$, where
  - $V$ is a set.
  - $E$ consists of pairs of elements in $V$.
- The elements of $V$ are called the *vertices* of $G$.
- The elements of $E$ are called the *edges* of $G$.
Graphs basic definition

- An edge spanning two vertices \( v \) and \( w \) is denoted \( e_{v,w} \).
- If \( e_{v,w} \in E \), we say that \( v \) and \( w \) are adjacent.
- The set of vertices adjacent to \( v \) is denoted \( \mathcal{N}(v) \).
Example

Figure 3: A drawing of an undirected graph with four vertices \{A, B, C, D\} and four edges \{e_{A,B}, e_{A,C}, e_{B,C}, e_{C,D}\}.
Example

Figure 4: The set $\mathcal{N}(A) = \{B, C\}$ of vertices adjacent to $A$. 
Images as graphs

- Graph based image processing methods typically operate on *pixel adjacency graphs*, i.e., graphs whose vertex set is the set of image elements, and whose edge set is given by an adjacency relation on the image elements.
- Commonly, the edge set is defined as all vertices $v, w$ such that

$$d(v, w) \leq \rho .$$

(1)
- This is called the *Euclidean adjacency relation*. 
Pixel adjacency graphs, 2D

Figure 5: A 2D image with $4 \times 4$ pixels.

Figure 6: A 4-connected pixel adjacency graph.

Figure 7: A 8-connected pixel adjacency graph.
Pixel adjacency graphs, 3D

Figure 8: A volume image with $3 \times 3 \times 3$ voxels.

Figure 9: A 6-connected voxel adjacency graph.

Figure 10: A 26-connected voxel adjacency graph.
Foveal sampling

“Space-variant sampling of visual input is ubiquitous in the higher vertebrate brain, because a large input space may be processed with high peak precision without requiring an unacceptably large brain mass.” [1]

Region adjacency graphs

Figure 13: An image divided into superpixels
Multi-scale image representation

*Resolution pyramids* can be used to perform image analysis on multiple scales. Rather than treating the layers of this pyramid independently, we can represent the entire pyramid as a graph.

Figure 14: A pyramid graph (Grady 2004).
Directed and undirected graphs

- The pairs of vertices in $E$ may be ordered or unordered.
  - In the former case, we say that $G$ is directed.
  - In the latter case, we say that $G$ is undirected.
- In this course, we will mainly consider undirected graphs.
Paths

- A *path* is an ordered sequence of vertices where each vertex is adjacent to the previous one.
- A path is *simple* if it has no repeated vertices.
- A *cycle* is a path where the start vertex is the same as the end vertex.
- A cycle is *simple* if it has no repeated vertices other than the endpoints.

Commonly, simplicity of paths and cycles is implied, i.e., the word “simple” is omitted.
Figure 15: A path $\pi = \langle A, D, E, H, I, F, E \rangle$. 
Example, Simple path

Figure 16: A simple path $\pi = \langle G, H, E, B, C \rangle$. 
Example, Cycle

Figure 17: A cycle $\pi = \langle A, B, E, F, E, D, A \rangle$. 
Example, Simple cycle

Figure 18: A simple cycle $\pi = \langle A, D, E, B, A \rangle$. 
Paths and connectedness

- Two vertices $v$ and $w$ are *linked* if there exists a path that starts at $v$ and ends at $w$. We use the notation $v \sim_w^G$. We can also say that $w$ is *reachable* from $v$.
- If all vertices in a graph are linked, then the graph is *connected*. 
Subgraphs and connected components

- If $G$ and $H$ are graphs such that $V(H) \subseteq V(G)$ and $E(H) \subseteq E(G)$, then $H$ is a subgraph of $G$.

- A subgraph $H$ of $G$ is said to be induced if, for any pair of vertices $v, w \in H$ it holds that $e_{v,w} \in E(H)$ iff $e_{v,w} \in E(G)$.

- If $H$ is a (induced) connected subgraph of $G$ and $v \not\sim_G w$ for all vertices $v \in H$ and $w \notin H$, then $H$ is a connected component of $G$. 
Example, connected components

Figure 19: A graph with three connected components.
Graph segmentation

- To segment an image represented as a graph, we want to partition the graph into a number of separate connected components.
- The partitioning can be described either as a *vertex labeling* or as a *graph cut*.
Vertex labeling

We associate each vertex with an element in some set $L$ of labels, e.g., $L = \{ \text{object, background} \}$.

**Definition, vertex labeling**

A (vertex) labeling $\mathcal{L}$ of $G$ is a map $\mathcal{L} : V \rightarrow L$.

Graph cuts

- Informally, a (graph) cut is a set of edges that, if they are removed from the graph, separate the graph into two or more connected components.

**Definition, Graph cuts**

Let $S \subseteq E$, and $G' = (V, E \setminus S)$. If, for all $e_{v,w} \in S$, it holds that $v \not\sim_{G'} w$, then $S$ is a (graph) cut on $G$. 

Example, cuts

Figure 20: A set of edge (red) that do not form a cut.
Example, cuts

![Graph of nodes connected by arrows, with one set of edges highlighted in red to indicate they do not form a cut.]

**Figure 21:** A set of edge (red) that do *not* form a cut.
Example, cuts

Figure 22: A set of edge (red) that form a cut.
A quick exercise

Let $G = (V, E)$. Is $E$ a cut on $G$?
Relation between labelings and cuts

Definition, labeling boundary

The boundary $\partial L$, of a vertex labeling is the edge set

$$\partial L = \{ e_{v,w} \in E \mid \mathcal{L}(v) \neq \mathcal{L}(w) \}.$$  

Theorem

For any graph $G = (V, E)$ and set of edges $S \subseteq E$, the following statements are equivalent*: [2]

1. There exists a vertex labeling $\mathcal{L}$ of $G$ such that $S = \partial \mathcal{L}$.
2. $S$ is a cut on $G$.

*) Provided that $|L|$ is “large enough”.

Relation between labelings and cuts

Figure 23: Duality between cuts and labelings.
Summary

- Basic graph theory
  - Directed and undirected graphs
  - Paths and connectedness
  - Subgraphs and connected components
- Images as graphs
  - Pixel adjacency graphs in 2D and 3D
  - Alternative graph constructions
- Graph partitioning
  - Vertex labeling and graph cuts
Next lecture

- Interactive image segmentation
- Intro to combinatorial optimization
